Deterministic Finite Automaton (*DFA*)

A Deterministic Finite Automaton (*DFA*) is the following 5-tuple: $A = (Q, \Sigma, \delta, q_0, F)$, where:

- Q is a finite set of states.
- Σ is a finite set of symbols called *alphabet*
- $\delta : Q \times \Sigma \rightarrow Q$ is a partial function called *transition function*.
- $q_0 \in Q$ is the *initial state*.
- $F \subseteq Q$ is the *set of final states*.

When the transition function is total the automaton is called *complete*.

Automata Representation:

Transition table

Finite
Automata

Computación

DFA

NFA

Equivalence
DFA — NFA

λ -FA

Equivalence
NFA — λ -FA

$|Q|$ rows and $|\Sigma|$ columns. (i, j) is the state $\delta(q_i, a_j)$ where q_i is the i th element of Q and a_j the j th element of Σ .

Example

Let $A = (\{q_0, q_1, q_2\}, \{a, b\}, \delta, q_0, \{q_0, q_1\})$ where δ is defined as follows:

$$\begin{array}{lll} \delta(q_0, a) = q_0 & \delta(q_1, a) = q_2 & \delta(q_2, a) = q_2 \\ \delta(q_0, b) = q_1 & \delta(q_1, b) = q_1 & \delta(q_2, b) = q_2 \end{array}$$

Its transition table is:

	a	b
q_0	q_0	q_1
q_1	q_2	q_1
q_2	q_2	q_2

Automata Representation:

DFA

NFA

Equivalence
DFA \rightarrow NFA

λ -FA

Equivalence
NFA \rightarrow λ -FA

Is a labeled directed graph, where:

- Its number of nodes (vertices) is $|Q|$. Every node corresponds to a state.
- $\forall q_i, q_j \in Q, \forall a_k \in \Sigma$, if $\delta(q_i, a_k) = q_j$ there is an arc (arrow) that goes from state q_i to state q_j labeled with a_k .
- The initial state has an input arrow coming from nowhere.
- The final states are drawn with a double circle.

The function $\hat{\delta} : Q \times \Sigma^* \rightarrow Q$ is defined as follows:

$$\forall q \in Q, x \in \Sigma^*, a \in \Sigma$$

- $\hat{\delta}(q, \lambda) = q$
- $\hat{\delta}(q, xa) = \delta(\hat{\delta}(q, x), a)$

As $\hat{\delta}(q, a) = \hat{\delta}(q, \lambda a) = \delta(\hat{\delta}(q, \lambda), a) = \delta(q, a)$, in the sequel, we will write δ instead of $\hat{\delta}$.

Language accepted by a DFA

- Let $A = (Q, \Sigma, \delta, q_0, F)$ be a DFA, and let $x \in \Sigma^*$. A string x is accepted by A when $\delta(q_0, x) \in F$.
- The *language accepted* by the DFA A is defined as:

$$L(A) = \{x \in \Sigma^* \mid \delta(q_0, x) \in F\}$$

Non Deterministic Finite Automata (NFA)

A Non Deterministic Finite Automata (NFA) is a 5-tuple

$A = (Q, \Sigma, \delta, q_0, F)$, where:

- $Q, \Sigma, q_0 \in Q$, y $F \subseteq Q$ are the same as in the definition of DFA's
- The transition function is now the partial function $\delta : Q \times \Sigma \rightarrow 2^Q$.

NFA Representation

Finite Automata

The function $\hat{\delta} : Q \times \Sigma^* \rightarrow 2^Q$ is defined as follows:

$\forall q \in Q, x \in \Sigma^*, a \in \Sigma :$

- $\hat{\delta}(q, \lambda) = \{q\}$
- $\hat{\delta}(q, xa) = \bigcup_{p \in \hat{\delta}(q, x)} \delta(p, a)$

As $\hat{\delta}(q, a) = \bigcup_{p \in \hat{\delta}(q, \lambda)} \delta(p, a) = \bigcup_{p \in \{q\}} \delta(p, a) = \delta(q, a)$, in the sequel we will use δ instead of $\hat{\delta}$.

Language accepted by a NFA

Let $A = (Q, \Sigma, \delta, q_0, F)$ a NFA, the *language accepted* by the NFA A is defined as

$$L(A) = \{x \in \Sigma^* \mid \delta(q_0, x) \cap F \neq \emptyset\}$$

λ -FA

Equivalence
NFA – λ -FA

- Every *DFA* is a particular instance of a *NFA*.
- The way to obtain an equivalent *DFA* from a *NFA* is based in the fact that the power set (set of subsets) of a finite set is also finite and thus:
 - The states of the *DFA* are subsets of the set of states of the *NFA*.
 - The transition function of a symbol acts between set of states.

Equivalence *DFA* – *NFA*

Let $A = (Q, \Sigma, \delta, q_0, F)$ be a *NFA* such that $L = L(A)$.

We define a *DFA* $A' = (Q', \Sigma, \delta', q'_0, F')$ as:

- $Q' = 2^Q, q'_0 = \{q_0\},$
- $F' = \{q' \in Q' \mid q' \cap F \neq \emptyset\},$
- The transition function δ' is defined as the extension of the function δ to set of states.
- The automaton A' so defined is a *DFA*, as its transition function is $\delta' : Q' \times \Sigma \rightarrow Q'.$
- It can be proved that $L(A') = L.$

λ -FA

Equivalence
NFA \rightarrow λ -FA

λ – closure

- λ – closure(q_0) = $\{q_0, q_1, q_2\}$
- λ – closure(q_1) = $\{q_1, q_2\}$
- λ – closure(q_2) = $\{q_2\}$
- λ – closure(q_3) = $\{q_0, q_1, q_2, q_3\}$

Example

Finite
Automata

U.D.
Computación

DFA

NFA

Equivalence
DFA \rightarrow NFA

λ -FA

Equivalence
NFA \rightarrow λ -FA

Calculus of $\hat{\delta}(q_0, 01)$

$$\hat{\delta}(q_0, 01) = \lambda - \text{closure}(\bigcup_{p \in \hat{\delta}(q_0, 0)} \delta(p, 1)) \quad (1)$$

$$\hat{\delta}(q_0, 0) = \lambda - \text{closure}(\bigcup_{p \in \hat{\delta}(q_0, \lambda)} \delta(p, 0)) \quad (2)$$

$$\hat{\delta}(q_0, \lambda) = \lambda - \text{closure}(q_0) = \{q_0, q_1, q_2\}.$$

Substituting in (2):

$$\begin{aligned} \hat{\delta}(q_0, 0) &= \lambda - \text{closure}(\bigcup_{p \in \{q_0, q_1, q_2\}} \delta(p, 0)) = \\ &= \lambda - \text{closure}(\emptyset \cup \emptyset \cup \{q_1\}) = \lambda - \text{closure}(\{q_1\}) = \{q_1, q_2\}. \end{aligned}$$

Substituting in (1):

$$\begin{aligned} \hat{\delta}(q_0, 01) &= \lambda - \text{closure}(\bigcup_{p \in \{q_1, q_2\}} \delta(p, 1)) = \\ &= \lambda - \text{closure}(\{q_2\} \cup \{q_3\}) = \lambda - \text{closure}(\{q_2, q_3\}) = \\ &= \{q_0, q_1, q_2, q_3\}. \end{aligned}$$

In a λ -FA, $\hat{\delta}(q, a)$ and $\delta(q, a)$ are not necessarily equal and the same happens to $\hat{\delta}(q, \lambda)$ and $\delta(q, \lambda)$.
we have to distinguish between δ and $\hat{\delta}$.

Language accepted by a λ -FA

Let $A = (Q, \Sigma, \delta, q_0, F)$ be a $FA\lambda$, we define the *Language accepted* by the $FA\lambda$ A as

$$L(A) = \{x \in \Sigma^* \mid \hat{\delta}(q_0, x) \cap F \neq \emptyset\}.$$

Equivalence $NFA - \lambda$ -FA

Finite
Automata

U.D.
Computación

DFA

NFA

Equivalence
DFA \rightarrow NFA

λ -FA

Equivalence
NFA \rightarrow λ -FA

Every NFA can be seen as a $FA\lambda$ in which
 $\forall q \in Q \quad \lambda - closure(q) = \{q\}.$

Equivalence $NFA - FA\lambda$

Let $A = (Q, \Sigma, \delta, q_0, F)$ be a $FA\lambda$. We define a NFA
 $A' = (Q, \Sigma, \delta', q_0, F')$ where:

$$F' = \begin{cases} F \cup \{q_0\} & \text{if } \lambda - closure(q_0) \cap F \neq \emptyset \\ F & \text{otherwise} \end{cases}$$

The function δ' is defined as:

$$\forall q \in Q, a \in \Sigma \quad \delta'(q, a) = \hat{\delta}(q, a).$$

Example
